A.L. 1

GENERAL DESCRIPTION

1.1 Concurrent with the present modernization programme underway in the Naval Service, the existing PV500HM2 transmitters are being modified to make their circuitry adaptable to the later types of ancillary equipment in use.

The incorporation of the following three modifications will result in the transmitters henceforth being known as PV500HM3.

1.2 MODIFICATION #1

It has become increasingly evident during the past few years that it would be necessary to fit whip antennae on H.M.C. Ships. The adaptation of existing equipment to whip antenna has necessitated modifying and moving to a remote point the antenna impedance matching network. In the former type of system, the antenna radiated from the position where it left the transmitter resulting in a high loss from standing waves in the trunking particularly on certain frequencies. In order to adapt whip antenna to existing equipment, it was necessary to fulfil the following three conditions:

- (a) To effect a match between the low impedance co-axial transmission line and the plate tank circuit of the transmitter. The use of this cable has the advantages of being easier to install and maintain, as well as having a much higher efficiency than trunking over a wide band of frequencies.
- (b) To locate the antenna coupling components between the co-axial cable and whip antenna, permitting the co-axial cable impedance to be matched to the whip antenna.
- (c) To add and subtract capacitive and inductive reactance to the whip by varying inductance and capacity ^{once} ~~in~~ ^{all} in order to cause it to resonate at the frequency of the transmitter.

Accomplish these adjustments from the transmitter, it is necessary, of course, that they be remotely controlled.

The antenna coupling circuits have therefore been removed from the transmitter proper and mounted on a separate chassis. This unit is then housed at the base of the whip antenna. Electro-mechanical devices control the rotation of the antenna tuning capacitor and the antenna tuning inductor rotary switches. The movements of the inductor rotary switches are repeated back to the transmitter by means of selsyn generators, thereby indicating to the operator the position of the switches in the remote coupling unit. Repeaters are mounted in the space in the transmitter formerly occupied by the antenna coupling section. Three lever control switches are mounted on the front of the transmitter cabinet directly above the metering panel. The variable antenna tuning capacitor is driven by a selsyn motor, which is in turn driven by a voltage produced by a selsyn generator attached to the antenna capacitor dial in the R.F. Unit. The ambient temperature in the supporting base of the antenna is kept at 70 degrees F. by the inclusion of electrical strip heaters which are thermostatically controlled.

(2)

1.3 MODIFICATION #2

Some difficulty has been evident in tuning of the PV500HM2 due mainly to the fact that on the low frequencies there was an excessive amount of grid excitation, to the final amplifier; while on the higher frequencies, there was insufficient. This resulted in the multiplier stage being de-tuned on the low frequencies in order to reduce the drive. This de-tuning, in many cases, resulted in the generation of harmonics and parasitics which subsequently appeared in the final plate tank circuit and were transferred to and radiated by the antenna. This has been reduced by the addition of a control tube which limits the drive to the final amplifier to a predetermined maximum which may be reduced by a potentiometer designated "Excitation" mounted on the front panel of the transmitter.

1.4 MODIFICATION #3

Transmitter PV500HM2 made no provision for the connecting of a Frequency Shift Keyer (which is necessary for the utilization of the equipment on RATT) to the oscillator control unit. This has been provided for in Transmitter PV500HM3 by the inclusion of a suitable "jack" on the front of the oscillator control panel, a three position switch, and a screw driver adjusted variable capacitor.

the new addition
+ power phone from oscillator set to remote

INSTALLATIONSECTION II:

2.1 The installation procedure for Transmitter PV500HM3 is similar to that of PV500HM2 with the exception that consideration must be given to the installation of the remote antenna coupling unit in a suitable housing at the base of the antenna. The design of this housing is to be in accordance with Esquimalt Drawing No. 3696.

2.2 Aerial trunking is not required in this installation. The radio frequency output of the transmitter is fed to the remote coupling unit by a co-axial cable type RG18/U. The length of co-axial cable utilized in installation is not critical but should be kept within reasonable limits as the attenuation will increase where excessive lengths are used. No special precautions in fitting the co-axial cable need be observed, other than those currently in use with co-axial cables, such as maintaining a minimum radius of bending, not allowing metal particles to become embedded in the polythene, and installing the cable in such a manner as to preclude the possibility of displacement of the inner conductor through softening of the polythene due to excessive heat. Three multi-core cables type MHEA-10 are required for the electrical control of the remote coupling mechanism. This cable contains conductors for:

- (a) Supplying alternating current of 115 volts 60 cycles for the operation of the mechanism, the heaters and the rotors of the selsyns.
- (b) The various tuning switches.
- (c) Sound power phone communication between the transmitter and the remote coupling unit.
- (d) Supplying voltage from the stators of the selsyns used as generators, to the stators of the selsyns used as motors.
- (e) Supplying power to a 115V 7 watt lamp on the indicator assembly through a switch on the variable capacitor assembly for the purpose of indicating to the operator when the variable capacitor is at minimum capacity.

SECTION III - OPERATION

3.1 The operation of the PV500HM3 is similar to that of the PV500HM2 with the following exceptions.

3.2 The power requirement to operate the antenna coupling mechanism at the base of the antenna is controlled by a switch at the left of the control unit panel and is indicated by an amber indicating light located on the same panel. The operation of the rotary ceramic switches in the remote antenna coupler is accomplished by three lever switches located at the top of the transmitter cabinet. These switches are marked from left to right as follows:

"R./COUPLING" (Remote Coupling)

"LOADING"

"ANT. TUNE" (Antenna Tune)

The PV500HM3 like the PV500HM2 has a total of five controls for the adjustment of the antenna circuits. The series tune capacitor C45A has been removed. A manual coupling switch has been fitted so that the PV500HM3 has two coupling controls whereas the PV500HM2 has one only. These are known as the "Local Coupling" and "Remote Coupling" controls. They are located at either end of the co-axial cable; one for link coupling the output of the transmitter into the co-axial cable and the other for coupling the co-axial cable to the antenna network.

The rotation of the remote rotary switches is accomplished by operating the appropriate lever switch. Pressure to the left will cause the corresponding rotary switch in the remote antenna coupling assembly to rotate one division in a counter-clockwise direction, while pressure to the right will cause the switch to rotate in a clockwise direction one division. Releasing the lever switch, permitting it to return to the neutral position, will allow repetition of the cycle.

3.3 The indicating repeaters are located on the right hand side of the radio frequency unit and consist of three selsyn motors. Attached to the shafts of the selsyn motors are three dials, which indicate to the operator the position of the three switches in the remote coupling mechanism. They are marked "R/Coupling", "Loading" and "Antenna Tune". Immediately below the three dials will be found the vernier dial marked "Antenna" which is used for adjusting the variable capacitor in the remote coupling mechanism. Through the use of a selsyn generator attached to the vernier dial, the selsyn motor attached to the variable capacitor is caused to take up a position indicated by the vernier dial. Directly above the "R/Coupling" dial is located the "Local Coupling" switch. This is a manually operated rotary switch which taps more or less turns in the coupling link and thus allows the coupling link to be tapped at the correct impedance point to match the co-axial cable over the frequency range of the PV500HM3.

3.4 Between the "R/Coupling" dial and the "Local Coupling" knob will be found a hole, behind which is located a lamp. By rotating the vernier dial marked "Antenna", the lamp can be made to "light up" when the vernier dial reads 10° (variable capacitor at minimum). Should the lamp light at any other position of the dial, it indicates the vernier dial has been rotated with the power off. To re-establish alignment of the dial with capacitor

turn the vernier dial until the lamp lights; turn the power to the remote coupling unit off and rotate the vernier dial to read 100. The two selsyns concerned will now be in alignment.

3.5 The general procedure for the tuning adjustments of the antenna circuit will follow what has been laid down in the PV500HM2 Handbook, Page 10, Section 2.26 with the exception of the adjustment of the series tuning capacitor.

3.6 A key operated lock is located at the right hand side of the oscillator control unit panel. The barrel of the lock has been arranged in such a manner as to engage a single throw toggle switch which is in series with the safety gate switches of the transmitter, breaking the primary supply of the high voltage circuits. This functions as a safety lock or "Safe to Transmit Board". The operation of the transmitter is not possible without the key being inserted and turned in the lock. The key cannot be removed in the "Safe to Transmit Position".

3.7 A jack has been provided in each unit to allow the use of a sound power telephone for communication between the transmitter and the antenna coupling unit.

3.8 The need for increased grid drive to the final amplifier on the higher frequencies has necessitated an additional 807 be fitted in parallel with the existing 807 driver. However, some means of controlling the amount of excessive drive on the lower frequencies is necessary. This has been accomplished by the addition of an 807 current control tube. A potentiometer installed on the radio frequency unit above the range switch makes the grid of the 807 control tube more or less positive, thereby effecting a control of the passage of current through the control tube. This tube is in series with the screen supply of the 807 driver stage. The potentiometer has been calibrated and is marked "EXCITATION". An additional wafer switch "D" ganged to "S 21" (the band change switch) taps resistances in or out in series with the potentiometer to limit grid current to approximately 40 MA.

3.9 The modification of the XTAL-MO circuit permits the introduction of a signal from a teletype Frequency Shift Keyer. The previous two position XTAL-MO switch has been removed and replaced with a three position switch designated on the front panel as "FSK-XTAL-MO".

A JONES connector has been fitted directly above the switch shaft into which the output of the Frequency Shift Keyer may be plugged. To the left is a variable capacitor which is screw-driver adjusted for the correct drive as indicated by a reading of 2 to 2.5 MA on position "one" of the multimeter.

3.10 - ADJUSTMENT PROCEDURE

- (A) Select the correct RANGE according to frequency.
- (B) Select the correct colour of RF GENERATOR.
- (C) Select XTAL, MO or FSK.
- (D)
 1. For XTAL, adjust RF GENERATOR for minimum oscillator plate and screen current in multimeter position 2.
 2. For MO, adjust RF GENERATOR to the correct reading for the frequency as shown on the calibration chart.
 3. For FSK, adjust RF GENERATOR to the approximate reading for the frequency as shown on the calibration chart. Apply the signal from the Frequency Shift Keyer; repeat the adjustment of the RF GENERATOR for maximum reading of the milli-ammeter in position one. Adjust the FSK series drive capacitor for a reading of 2.0 to 2.5 MA with the multimeter in position one.
- (E) Adjust the multiplier for maximum driver cathode current.
- (F) Adjust the driver for maximum grid current to the final amplifier, then adjust the "EXCITATION CONTROL" so that the final grid current is approximately 25 MA. Note that pos. 5 of the multiplier is now multiplied by 2.
- (G) Adjust P-A condenser for minimum cathode currents.
- (H) ~~Adjust the "Antenna Condenser", "Antenna Tune", "Loading" and both "Coupling Controls" for maximum antenna current on the 0.5 RANGE of the RF Ammeter with the power amplifier ADJUST-OPERATE switch in the ADJUST position.~~
- (I) ~~Adjust ANTENNA condenser, ANT. TUNE, LOADING, and COUPLING controls for maximum antenna current (on 0.5 amp. range) when the power amplifier is tuned and the ADJUST-OPERATE switch in the ADJUST position,~~
- (J) Switch the ANTENNA METER to the 10 amp. range, switch to OPERATE and make adjustments until both of the P.A. cathode meters read 240 MA. when the P.A. condenser is tuned to maximum antenna current. With the multimeter on position 5, check that the grid current to the final tubes is 25 milli-amperes.

SECTION 4 - MECHANICAL DESCRIPTION - Antenna Coupler Mechanism

4.1 This section deals with the transmission of power from the main motor to the antenna coupling switches and is comprised of four parts, namely;

- (A) Motor and Safety Clutch.
- (B) Eccentric clutch assembly.
- (C) Escapement plate and pawls.
- (D) Ratchet wheels.

4.2 (A) The motor and safety clutch mechanism consists of an alternating current motor coupled to the safety clutch shaft by means of a worm and worm wheel. The front end of the safety clutch shaft is fitted into a bronze bearing in the safety clutch hub. A pin through this shaft engages a slot in the safety clutch drive plate.

4.2 (B) The component parts of the eccentric clutch assembly are mounted on a shaft and are driven by the safety clutch. The shaft is fitted into the safety clutch hub and secured by a set-screw. Bearings for the shaft are fitted in the back plate and in the centre bearing block adjacent to the safety clutch. The escapement eccentric clutch is divided into two parts. The front half or driving section, is pinned to the shaft, while the rear half, or driven section idles on the shaft. The driven section of the clutch, when disengaged, is in a neutral position and is held stationary by the clutch pawl engaging a detent on the circumference of the driven section of the clutch. Releasing the clutch pawl from detent causes the driven section of the clutch to move towards the driving section, being assisted by the pressure of a spring on the back face of the driven section. The faces of both halves of the clutch are of a saw tooth design, and their engaging causes the clutch to revolve as a whole. At the end of one revolution of the eccentric clutch, the clutch pawl will engage the detent and cause the driven section of the eccentric clutch to stop rotating and to become disengaged from the driving section of the eccentric clutch.

4.2 (C) At the instant of engagement of the clutch pawl with the detent, the subsequent motion of the eccentric clutch as a whole is transmitted to the escapement plate through the connecting rod and the escapement eccentric. The escapement plate is thereby caused to make a downward motion and in so doing causes a pawl at either side of the escapement plate to drag one of the ratchet wheels in a clockwise or anti-clockwise direction for thirty-six degrees of rotation. The escapement plate having completed the length of its downward stroke proceeds to move back up to its starting position, and in so doing causes the pawl to disengage itself from the tooth of the ratchet wheel. Since the rotational force that is used to drive the escapement plate down and up is removed some degree before the plate has completed its upward motion, a spring is fitted between the connecting rod and a pin on the rear vertical support plate which pulls the connecting rod to its completion of 360 degrees of rotation.

4.2 (D) The rotation of the ratchet wheels causes the ceramic wafer switches to rotate a like amount with the assistance of the star wheels attached to the switch shaft directly in front of the switch.

SECTION V - TECHNICAL DESCRIPTION

5.1 This section outlines the preventive maintenance, adjustment and replacement procedure of the mechanical components.

5.2 Lubrication:

Oil - 3-GP-37

Grease - Normal #51

Main Motor - 2 drops oil - every 100 operating hours.

switch shaft bearings - grease - every 100 operating hours.

Switch Sprocket Wheels - grease - every 100 operating hours.

Clutch Shaft Bearings - 1 drop oil - every 50 operating hours.

Worm and Fibre Gear - Grease - every 100 operating hours.

Solenoid armature shaft Bogey Wheels - 1 drop oil - every 100
operating hours.

All Moving Parts Escapement Plate - 1 drop - every 100 operating
hours.

Connecting Rod - 2 drops - every 100 operating hours.

Grease or Oil MUST NOT be applied to any switches, solenoid
armatures, selsyn motors or generators.

5.3 SAFETY CLUTCH

In the event of any component of the eccentric clutch, escapement plate, escapement plate pawls, ratchet wheels or rotary switches becoming jammed, the mechanism would cease to function and cause the main motor to stop. As a protection against this, and to prevent subsequent motor breakdown, a safety clutch has been fitted between the motor and the escapement assembly. The SAFETY CLUTCH is a friction drive type and will permit the motor to continue to rotate though the mechanism is jammed. It is necessary that the correct amount of internal pressure be applied by the spring upon the pressure plate of the safety clutch so that the clutch will neither slip when being driven under normal conditions nor will it grip when the mechanism becomes locked.

To adjust the safety clutch, loosen the grub screw located on the adjusting cap. Holding the drum hub in the left hand, adjust the knurled cap to acquire the desired amount of friction. Sufficient friction must be obtained so that no slippage will occur through normal operation. To test the friction, place the machine in motion by depressing the clutch throw-out pawl. Place a hand on the top of the escapement plate and press down momentarily, the clutch should then slip before the motor will stall.

5.4 ADJUSTMENT OF INNER AND OUTER ESCAPEMENT PLATE PAWL STOPS

The outer pawl eccentric stops are to be adjusted so that the pawl driving pin will clear the circumference of the ratchet wheel by a minimum of .0625 (plus or minus .01).

The inner pawl eccentric stops are to be adjusted so that a clearance of .005 of an inch should be maintained between the pawl pin and the inner face of the ratchet wheel detent.

5.5 REPLACEMENT AND ADJUSTMENT OF THE ESCAPEMENT PAWL SOLENOID

To replace the pawl solenoids, unsolder the wires attached to the solenoid. Remove the armature guide screw and withdraw the armature from the solenoid taking care that the armature drive shaft does not become bent. Remove the solenoid retaining clamp, and the screw that holds the solenoid. This screw is accessible from the back of the rear plate. Place the new solenoid in position and secure. Replace retaining clamp, armature and guide screw.

5.6 REPLACEMENT AND ADJUSTMENT OF MICRO-SWITCHES

Remove screws holding micro-switch mounting block, which are accessible from rear of plate. Unsolder wires to upper terminals. Remove both micro-switch retaining screws, taking care to retain actuator, and both clamping plates. Put screws, which should be through the outer clamping plate, through the new micro-switch and attach to block by threading screws into rear clamping plate. Place micro-switch mounting block in position and replace screws. Having fastened the micro-switch in position, press the armature of the solenoid in towards the pawl and make certain that the micro-switch clicks into the "on" position when the pawl driving pin does not exceed more than .0625 of an inch from the inner face of the ratchet wheel tooth. Should the micro-switch click into the "on" position before the pawl driving pin has engaged the ratchet wheel tooth, the mechanism will operate and the pawl driving pin not having engaged the tooth, will leave the ratchet wheel and rotary switch in the same position. When the exact location of the micro-switch has been established, tighten micro-switch retaining screws.

5.7 ADJUSTMENT OF THE ESCAPMENT PAWL RETURN SPRING

Too great a pull by the spring on the escapement pawl will cause it to be difficult for the escapement pawl solenoid to drive the pawl into the ratchet wheel. Therefore, it is necessary that they be adjusted by repositioning the spring retaining bracket. Conversely the springs should have sufficient tension to make the pawl break away from the ratchet wheel cleanly, without hesitation.

SECTION VI - ELECTRICAL MAINTENANCE

6.1 Little difficulty should be experienced with the maintenance of the electrical components within the mechanism. That which will be necessary will be the normal replacement of defective components, such as capacitors, selenium rectifiers, switches, solenoids, etc.

6.2 SOLENOID D/C SUPPLIED

There are two selenium rectifier assemblies utilized during the operation of the remote control coupling unit. These are RS1 and RS2 and are mounted at the rear underside of the variable capacitor base. RS1 supplies direct current to L 39, the clutch trip solenoid; while RS2 supplies direct current to L 33-38, the pawl driving solenoids.

6.3 FUSES

The PV500HM3 has four additional fuses. Two of these will be found immediately above the power supply on the right hand side of the transmitter case. They are rated at 10 amperes and used for the protection of the remote coupling unit and the indicator assembly. The remaining two fuses are for the protection of the selsyns. The selsyns, eight in number, are divided into two groups of four. One group in the remote coupling mechanism, which has all four rotors connected in series across 115 volts 60 cycles, is fused by a 3AG 2 ampere fuse mounted on the front end of the variable capacitor base plate. The other four selsyns are mounted in the indicator assembly. They are protected by a similar fuse 3AG 2 ampere mounted on the front vertical plate of the indicator assembly.
